Type 1290 Vapor Recovery Regulator

Figure 1. Type 1290 Vapor Recovery Regulator

Features

Quick-Change Trim Package—Tested trim packages can be ordered and stocked ahead of time for fast replacement.

Easy In-Line Maintenance—Top-entry design reduces maintenance time and manpower requirements; trim parts can be inspected, cleaned and replaced without removing the body from the line.

In-Service Travel Inspection—Standard travel indicator assembly with protective cover permits periodic inspection of plug travel without removing regulator from service. It can also be used for remote alarming and monitoring stem position when combined with the Topworx™ 4310 wireless position monitor. The Position Monitor Bracket (PMB) Mounting Kit is required; reference document D103260X012 for more details.

High Accuracy—Total proportional band of 0.25 in. w.c. / 0.62 mbar or less at lower set pressures.

Proven Technology—Time-proven regulator technology has been adapted to meet the specific requirements of vapor recovery (depaddng) applications.

Arctic Temperature Constructions—For process temperatures as low as -76°F / -60°C.

Introduction

The Type 1290 vapor recovery regulator controls vessel blanketing gas pressure when the vessel is being filled with fluid or when ambient temperature causes the vapor gas to expand. The system monitors the increasing blanket pressure and throttles open to pass excess blanketing gas into a vapor disposal or reclamation system thus controlling the desired set pressure of the vessel.

Note

The vapor recovery regulator is not intended to be used as an ASME certified relief device for overpressure protection.

The vapor recovery regulator responds to any changes in the blanket gas pressure and throttles open or closed to control the flow of the blanket gas out of the vessel. A vacuum source on the outlet of the regulator is usually necessary to ensure flow of low pressure blanket gas out of the vessel into a vapor disposal or reclamation system. The higher the vacuum pressure of the vacuum source, the higher the flow capacity of the vapor recovery regulator.

Type 1290

Specifications

This section lists the specifications for the Type 1290 Vapor Recovery Regulator. Specifications for a given regulator as it originally comes from the factory are stamped on the regulator nameplate located on the actuator, while the pilot control spring range appears on the pilot spring case nameplate.

1. End connections for other than U.S. standards can usually be provided. Consult your local Sales Office.

2. The pressure/temperature limits in this Bulletin and any applicable standard or code limitation should not be exceeded.

3. Special low temperature constructions for process temperatures between -76 to 180°F / -60 to 82°C are available by request. The low temperature construction passed Emerson laboratory testing for lockup and external leakage down to -76°F / -60°C.

Principle of Operation

The Type 1290 vapor recovery regulator serves as a vessel vapor recovery system. The Type 1290 regulator controls vessel blanketing gas pressure when the vessel is being filled with fluid or when ambient temperature causes the vapor gas to expand.

The system monitors the increasing blanket pressure and throttles open to pass excess blanketing gas into a vapor recovery system thus controlling the desired set pressure of the vessel.

Inconel® is a mark owned by Special Metals Corporation.

Table 7. Flow Rate Conversions (Gas Flow Required to Displace Blanketing Gas with Pump-in of Liquid)⁽¹⁾

MULTIPLY MAXIMUM PUMP RATE IN	BY	TO OBTAIN
U.S. GPM	8.021	SCFH air required ⁽²⁾
U.S. GPH	0.1337	
Barrels/hour	5.615	
Barrels/day	0.2340	

1. For liquids with a flash point below 100°F / 38°C or normal boiling point below 300°F / 149°C, multiply the above calculated outbreathing requirement by 2.0.
 2. To convert to Nm³/h, multiply SCFH by 0.0268.

Note

The Type 1290 Vapor Recovery Regulator is not intended to be used as an ASME certified relief device for overpressure protection. It is to be used as part of the gas blanketing system to control the outflow of blanketing gas under normal conditions and to collect vessel vapors for the vapor recovery system. You should provide alternate methods of emergency overpressure protection.

The Type 1290 Vapor Recovery Regulator responds to any changes in the blanket gas pressure and throttles open or closed to control the flow of the blanket gas out of the vessel. A vacuum source on the outlet of the regulator is usually necessary to ensure flow of low pressure blanket gas out of the vessel into a vapor recovery system. The higher the vacuum pressure of the vacuum source, the higher the flow capacity of the vapor recovery regulator.

The pressure of the blanket gas registers under the diaphragm of the pilot. A Type MR95H regulator provides a constant loading pressure source to the Type 1098 actuator.

When the pilot is closed, the loading pressure fills both sides of the Type 1098 actuator through a fixed restriction.

The Type EGR main valve spring keeps the main valve plug tightly shut off. When the vessel blanket gas pressure reaches the setting of the pilot spring, the pilot diaphragm moves, opening the pilot valve disk and exhausting some of the Type 1098's actuator loading pressure through the pilot orifice. This typically happens when the vessel is being filled with liquid.

The small fixed restriction maintains a higher loading pressure on the bottom of the Type 1098 actuator. The pressure differential across the main valve diaphragm moves the diaphragm upward causing the main valve to open which allows the blanket gas to flow out to the vapor recovery system vacuum source, hence controlling the vessel blanket pressure.

When the vessel blanket gas pressure begins to stabilize, the pilot spring throttles the pilot disk closed. This allows the loading pressure source to fill both sides of the Type 1098 actuator through the fixed restriction. This equalizes the pressure acting on the diaphragm, thus allowing the main valve spring to close the main valve plug.

Type 1290

Sizing Blanketing Systems

When sizing a gas vapor recovery regulator system, you must consider the volume of blanketing gas that must be displaced from the vessel when either filling the vessel with liquid (pump-in) or the expansion of vapors inside the vessel during atmospheric thermal heating.

Using the established procedures from American Petroleum Institute Standard 2000 (API 2000), determine the flow rate for outbreathing.

1. Determine the flow rate of blanketing gas displaced when liquid is being pumped into the vessel (see Table 7).
2. Determine the gas flow rate due to outbreathing caused by atmospheric thermal heating (see Table 8).
3. Add the requirements of 1 and 2 and select a vapor recovery regulator size based on total capacity required from Table 5.

Sample Sizing Problem for Vapor Recovery Applications:

Vessel Capacity 1000 barrels
 Pump in Capacity 20 GPM / 75.7 lpm
 Inlet Pressure Source 60 psig / 4.1 bar nitrogen
 Desired Blanket Setpoint 0.5 in. w.c. / 1 mbar
 Desired Vapor Recovery Setpoint 2 in. w.c. / 5 mbar
 Vapor Recovery Vacuum Source 5 in. Hg / 169 mbar
 Fluid Hexane
 Boiling Point 155°F / 68°C

1. From Table 7 the desired air flow rate due to pump in equals 20 GPM x 8.021 x 2 = 320 SCFH / 8.58 Nm³/h air.

2. From Table 8 the desired air flow rate = 1000 SCFH / 26.8 Nm³/h air due to thermal heating.
3. Total required flow rate = 1000 SCFH air + 320 SCFH = 1320 SCFH / 35.4 Nm³/h air. This converts to nitrogen requirements of 1340 SCFH / 35.9 Nm³/h.

Capacity Information

Table 5 gives typical nitrogen regulating capacities at selected inlet pressures and outlet pressure settings. Flows are in SCFH (at 60°F and 14.7 psia) and Nm³/h (at 0°C and 1.01325 bar) of 0.97 specific gravity nitrogen. For gases of other specific gravities, multiply the given capacity of nitrogen by 0.985 and divide by the square root of the appropriate specific gravity of the gas required. To determine regulating capacities at pressure settings not given or to determine wide-open flow capacities, use the following formula:

$$Q = \sqrt{\frac{520}{GT}} C_g P_1 \sin \left[\frac{3417}{C_1} \sqrt{\frac{\Delta P}{P_1}} \right] \text{ Deg}$$

where:

- C_g = gas sizing coefficient from Table 6
- C₁ = C_g/C_v or 35 from Table 6
- G = gas specific gravity (air = 1.0)
- P₁ = absolute inlet pressure, psia (add 14.7 psi to gauge inlet pressure to obtain absolute inlet pressure)
- Q = flow rate, SCFH
- T = absolute temperature in °R of gas at inlet (°F + 460)

Installation

Using a straight run of pipe the same size or larger than the regulator body, install the Type 1290 regulator as shown in Figure 1 so that flow through the main valve body matches the flow arrow cast on the body. A control and exhaust line as in Figure 2 is required. If a block valve is required, install

a full flow valve between the regulator and the blanketed vessel. For proper operation at low setpoint ranges, the regulators should be installed with the pilot spring case barrel pointed down.
